CHAPTER 3

On the Coupling of Viscous and Inviscid Models for Compressible Fluid Flows Via Domain Decomposition
R. Glowinski*
J. Periaux†
G. Terrasson**

Abstract. We discuss in this paper the coupling between the Navier-Stokes equations modelling compressible viscous flows with the time dependent full potential equation modelling compressible potential flows. The coupling is done through a domain decomposition procedure with overlapping; with such an approach one can take advantage of operator splitting techniques for the time discretization of the above equations.

Numerical results obtained from finite element approximations are presented showing that the present method provides a good quality matching technique.

The main goal of this paper is to present a computational method for the coupling of two distinct mathematical models describing the same physical phenomenon, namely the flow of a compressible viscous fluid. The basic idea is to replace the Navier-Stokes equations by the potential one in those regions where we can neglect the viscous effects and where the vorticity is small.

Consider for example a flow around an airfoil; we can split the computational domain into two overlapping subdomains:

—A first one, containing the airfoil, where the flow is modelled by the Navier-Stokes equations;

*Department of Mathematics University of Houston, Houston, TX 77204-3476 and Paris VI and INRIA, France.
†Avions Marcel Dassault, Saint-Cloud, France, and INRIA.
**Avions Marcel Dassault, Saint Cloud, France.
A second, that we suppose to be sufficiently far from the airfoil so that the Navier-Stokes equations reduce there to the full potential equation for the velocity potential (assuming of course that in this second region, the flow is vorticity free).

Our goal here is to discuss a method for coupling both the Navier-Stokes and the full potential equations for compressible fluids. We will therefore describe the continuous equations, and then using a time discretization by operator splitting of the two sets of governing equations, reduce the original problem to a sequence of matching problems for linear models.

Then we will solve the matching problems by a GMRES type algorithm.

The possibilities of such techniques will be illustrated by the results of numerical experiments for 2-D flows around airfoils and/or inside air intakes.

2.1. The compressible Navier-Stokes equations.

Let us consider the unsteady flow of a compressible viscous fluid around the body B (as shown on Figure 2.1, below):

![Figure 2.1](image)

Flow around an airfoil B

We can use for the modelling of such flow the following (non conservative) system of partial
differential equations:

\[
\begin{align*}
(2.1) & \quad \frac{\partial \rho}{\partial t} + \nabla \cdot (\rho \mathbf{u}) = 0 \text{ in } \Omega (= \mathbb{R}^N \setminus \mathcal{B}), \\
(2.2) & \quad \rho \frac{\partial \mathbf{u}}{\partial t} + \rho (\mathbf{u} \cdot \nabla) \mathbf{u} + (\gamma - 1) \nabla \rho T = \frac{1}{\text{Re}} \left[ \nabla^2 \mathbf{u} + \frac{1}{3} \nabla (\nabla \cdot \mathbf{u}) \right] \text{ in } \Omega, \\
(2.3) & \quad \rho \frac{\partial T}{\partial t} + \rho \mathbf{u} \cdot \nabla T + (\gamma - 1) \rho \mathbf{u} \cdot \nabla \cdot \mathbf{u} = \frac{1}{\text{Pr}} \left[ \nabla^2 T + F(\nabla u) \right] \text{ in } \Omega,
\end{align*}
\]

where the pressure \( p \), the density \( \rho \) and temperature \( T \) satisfy the perfect gas law

\[
(2.4) \quad p = (\gamma - 1) \rho T \quad (\text{with } \gamma = 1.4 \text{ in air}).
\]

In (2.1), (2.3), \( \rho, u = \{u_i\}_{i=1}^N \quad (N = 2,3) \), \( T \) are the non-dimensionalized density, velocity and temperature, respectively, with (if \( N = 2 \))

\[
(2.5) \quad F(\nabla u) = \frac{4}{3} \left( \frac{\partial u_1}{\partial x_1} \right)^2 + \left( \frac{\partial u_2}{\partial x_2} \right)^2 + \frac{\partial u_1}{\partial x_1} \frac{\partial u_2}{\partial x_2} + \frac{\partial u_1}{\partial x_1} \frac{\partial u_2}{\partial x_2}.
\]

In the above equations \( \text{Re}, \text{Pr} \) and \( \gamma \) are the Reynolds number, the Prandtl number, and the ratio of specific heats, respectively.

From \( \Gamma_{\infty} \), we define

\[
(2.6) \quad \Gamma_{\infty}^- = \{ x | x \in \Gamma_\infty, \mathbf{u}_{\infty} \cdot n_{\infty}(x) < 0 \}, \quad \Gamma_{\infty}^+ = \{ x | x \in \Gamma_\infty, \mathbf{u}_{\infty} \cdot n_{\infty}(x) \geq 0 \}.
\]

\( (n_{\infty}(x)) \) = unit outward normal vector at \( \Gamma_{\infty} \), at \( x \), and we prescribe on the inflow boundary \( \Gamma_{\infty}^- \)

\[
(2.7) \quad u = u_{\infty}, \quad \rho = 1, \quad T = 1/(\gamma - 1)M_{\infty}^2,
\]

while on the outflow boundary \( \Gamma_{\infty}^+ \), we prescribe Neumann and other "natural" boundary conditions.

On the wall \( \Gamma_B \) we shall use the following Dirichlet boundary conditions
\[ u = 0, \quad T = T_\infty \left( 1 + \frac{7-1}{2} M_\infty^2 \right) \]

In (2.7), (2.8), \( u_\infty, T_\infty, M_\infty \) denote the free stream velocity, temperature and Mach number, respectively. Finally, we shall also prescribe the following initial conditions

\[ \rho(x, 0) = \rho_0(x), \quad u(x, 0) = u_0(x), \quad T(x, 0) = T_0(x). \]

In order to render the above system of equations close to the incompressible flow model, we introduce the following new dependent variables

\[ \sigma = \ln \rho \quad (\sigma: \text{logarithmic density}). \]

With this new variable, the Navier-Stokes equations become

\[ \frac{\partial \sigma}{\partial t} + \nabla \cdot u + u \cdot \nabla \sigma = 0, \]

\[ \frac{\partial u}{\partial t} + (u \cdot \nabla) u + (\gamma - 1)(T \nabla \sigma + \nabla T) = \frac{\nu}{\text{Re}} \left( \nabla^2 u + \frac{1}{3} \nabla (\nabla \cdot u) \right), \]

\[ \frac{\partial T}{\partial t} + u \cdot \nabla T + (\gamma - 1) T \nabla \cdot u = \frac{\nu}{\text{Re}} \left( \frac{\gamma}{\text{Pr}} \nabla^2 T + F(\nabla u) \right). \]

Equations (2.12), (2.13) can also be written as follows:

\[ \frac{\partial u}{\partial t} - \nu \nabla^2 u + \beta \nabla \sigma = \psi(\sigma, u, T), \]

\[ \frac{\partial T}{\partial t} - \Pi \nabla^2 T = \chi(\sigma, u, T), \]

with:

(a) \( \delta \): a mean value of the reciprocal of the density (\( \delta = 1 \) is a possible value),

(b) \( \nu = \frac{1}{\text{Re}}, \mu = \nu \delta, \Pi = \frac{\gamma \nu \delta}{\text{Pr}} \).
2.2. The time dependent full potential equation.

If we suppose that viscosity and vorticity can be neglected, then the corresponding flow which is inviscid and potential is governed by the following full potential equations:

\( \frac{\partial \rho}{\partial t} + \nabla \cdot \rho \mathbf{u} = 0, \)

\( \rho = \rho_0 \left( 1 - k(\| \nabla \varphi \|^2 + 2 \frac{\partial \varphi}{\partial t}) \right), \)

\( T = T_\infty + \frac{1}{2\gamma} \left( 1 - \| \nabla \varphi \|^2 - 2 \frac{\partial \varphi}{\partial t} \right). \)

In (2.17), (2.18), \( \varphi \) is the \textit{velocity potential}; it satisfies

\( \mathbf{u} = \nabla \varphi. \)

In the above equations, \( \rho_0 \) is the flow density at rest, and

\( T_\infty = \frac{1}{\gamma (\gamma - 1) M_\infty^2}, \)

\( k = \frac{\gamma - 1}{\gamma + 1} \frac{1}{C_s^2}, \)

\( \alpha = \frac{1}{(\gamma - 1)}. \)

\( \gamma: \text{ ratio of specific heats}, \)

For such \( \rho \frac{\partial \varphi}{\partial n} \)

\( \frac{\partial \varphi}{\partial n} \)

\( \mathbf{u} = \mathbf{u} \)

If we assume corresponding bo

\( \frac{\partial \varphi}{\partial n} \)

where \( n_\infty \) denote

We decr

\( \Omega_2, \) such that th

Figure 2.2, below

In Figure 2.2:
\[(2.24)\] \( C_\phi: \) critical velocity, \( M_\infty: \) Mach number at infinity.

For such a flow it is necessary to add boundary conditions such as

\[(2.25)\] \( \rho \frac{\partial \varphi}{\partial n} = 0 \) on \( \Gamma_B. \)

\[(2.26)\] \( \mathbf{u} = u_\infty, \rho = \rho_0(1 - k|u_\infty|^2)^\alpha = \rho_\infty \) at infinity.

If we assume that the potential flow region contains \( \Gamma_\infty \), partly or entirely, we shall take as corresponding boundary condition

\[(2.27)\] \( \rho \frac{\partial \varphi}{\partial n} = \rho_\infty u_\infty \cdot n_\infty \) on \( \Gamma_\infty, \)

where \( n_\infty \) denotes the unit outward normal vector at \( \Gamma_\infty. \)

We decompose the computational domain (still denoted by \( \Omega \)) into two subdomains, \( \Omega_1 \) and \( \Omega_2 \), such that the flow is governed by (2.1)-(2.4) in \( \Omega_2 \), and by (2.16)-(2.19) in \( \Omega_1 \). Notation is like in Figure 2.2, below:

\[ \text{Figure 2.2} \]
Decomposition of the computational domain

In Figure 2.2:
(a) $\Omega_{12} = \Omega_1 \cap \Omega_2$.

(b) $\gamma_1$ and $\gamma_2$ are the interfaces between $\Omega_{12}$ and $\Omega_2$, $\Omega_{12}$ and $\Omega_1$, respectively.

(c) $\Gamma_1 = \Gamma_{\infty} \cap \partial \Omega_1$, $\Gamma_2 = \Gamma_{\infty} \cap \partial \Omega_2$.

Our goal here is to solve (2.1)-(2.4) in $\Omega_2$, coupled to (2.16)-(2.19) in $\Omega_1$.

Actually, some extra boundary conditions have to be specified to obtain well-posed problems for $\{\sigma, u, T\}$ and $\varphi$; we shall take

\begin{align}
\varphi &= \psi \text{ on } \gamma_1, \\
u &= \nu, \quad T = r \text{ on } \gamma_2.
\end{align}

The problems associated to the trace of $\sigma$ (or $\rho$) on $\gamma_2$ are more delicate and will be discussed later on; indeed the operator splitting approach will provide this information automatically. If the (yet unknown) traces $\psi$ and $\{v, r\}$ are specified, in (2.28), (2.29), then $\varphi$ and $\{\sigma, u, T\}$ can be computed via equations (2.16)-(2.18) (on $\Omega_1$) and (2.11)-(2.13) (on $\Omega_2$), respectively.

In order to compute $\psi$ and $\{v, r\}$, and couple the two models, we can use a least squares approach in which we minimize over the overlapping region $\Omega_{12}$ some distance between $u$ and $\nabla \varphi$, and, also, $T$ and $T(\varphi)$. This minimization problem takes the following form

\begin{align}
\text{Find } \bar{\psi} \text{ and } \{\bar{v}, \bar{r}\} \text{ such that}
\end{align}

\begin{align}
J(\bar{\psi}, \bar{v}, \bar{r}) \leq J(\psi, v, r), \quad \forall (\psi, v, r),
\end{align}

where in (2.30) we have (with $A$ and $B$ two positive weights):

\begin{align}
J(\psi, v, r) &= \frac{1}{2} \int_{\Omega_{12}} |u - \nabla \phi|^2 dx + \frac{A}{2} \int_{\Omega_2} (T - T(\varphi))^2 dx,
\end{align}

where $\{u, T\}$ (resp. $\{\bar{u}, \bar{T}\}$) is the solution in $\Omega_2$ of the Navier-Stokes equations associated to $\{v, r\}$ (resp. $\{\bar{v}, \bar{r}\}$), with a similar definition for $\varphi$ and $\bar{\varphi}$.

To solve time discretization techniques; with a matching problem:

Remark 2.1: Further questions, concern the choice of least square approximated by

Remark 2.2: Pro L. Lions [1]; how (2.31) leads to qu derivative free m complicated.

Remark 2.3: The

(i) The cost $f$ complicated.

(ii) Formulation

For the $a'$

We define

\begin{align}
(2.32)_1 &< f_1, \\
(2.32)_2 &< f_2, \\
(2.32)_3 &< f_3,
\end{align}

In the re spaces, and $< \cdot, \cdot$. 

To solve this matching problem which is definitely nonlinear, we shall take advantage of a
time discretization of the Navier-Stokes and full potential equations, based on operator splitting
techniques; with such an approach, the time dependent coupling problem is reduced to a sequence of
matching problems for linear time independent equations.

Remark 2.1: From a theoretical point of view, the above least squares formulation raises several
questions, concerning, in particular the well posedness of the above problem, and more generally the
choice of least squares criteria J(·) and functional spaces for which problem (2.30) makes sense. Indeed
the above formulation makes sense for the finite element approximations of (2.30), (2.31).

Remark 2.2: Problem (2.30), (2.31) has the structure of an optimal control problem in the sense of J.
L. Lions [1]; however unlike the incompressible case, previously discussed in [2], the solution of (2.30),
(2.31) leads to quite complicated adjoint equations. Therefore, in practice, we shall systematically use
derivative free methods, like those variants of the GMRES algorithm in which partial derivatives are
approximated by finite differences (cf. [3]).

Remark 2.3: The minimization problem (2.30) is fairly complicated for the following reasons:
(i) The cost function (2.31) is non quadratic and the calculation of its derivative is rather
complicated.
(ii) Formulation (2.30), (2.31) requires the adjustment of the weighting parameter A.

For the above reasons, we have chosen the following variant of the coupling problem:

We define first residual functions \( f_1, f_2, f_3 \), as follows:

\[
\begin{align*}
(2.32)_1 \quad &<f_1, w_1> = \int_{\Omega_1} (\nabla \varphi - u) \cdot \nabla w_1 \ dx, \ \forall \ w_1 \in V_1; \ f_1 \in V_1', \\
(2.32)_2 \quad &<f_2, w_2> = \int_{\Omega_1} (u - \nabla \varphi) \cdot w_2 \ dx, \ \forall \ w_2 \in V_2; \ f_2 \in V_2', \\
(2.32)_3 \quad &<f_3, w_3> = \int_{\Omega_1} (T-T(\varphi)) w_3 \ dx, \ \forall \ w_3 \in V_3; \ f_3 \in V_3'.
\end{align*}
\]

In the relations (2.32), the \( V_i \) are appropriate functional spaces with the \( V_i' \) as their dual
spaces, and \(<\cdot, \cdot>,_i\) denotes the duality pairing between \( V_i' \) and \( V_i \). The \( f_i \)'s appear then as residuals
associated to the coupling terms. Of course the ideal matching would be the one for which the above \( f_i \)'s vanish simultaneously; in practice, we shall force them to be as small as possible, through a preconditioned GMRES algorithm to be described in Section 5.

3. Time discretization of the matching problem via operator splitting.

3.1. A time discretization of the compressible Navier-Stokes equations.

Following [4], we describe here a time discretization of the unsteady Navier-Stokes equations (2.1)-(2.4) in \( \Omega_2 \), based on operator splitting methods.

Let \( \Delta t > 0 \) be a time discretization step; with \( \theta \in (0, \frac{1}{2}) \), define \( a \) and \( b \) by

\[
(3.1) \quad a = (1 - 2\theta)/(1 - \theta), \quad b = \theta/(1 - \theta).
\]

Then, with obvious notation, we approximate the compressible Navier-Stokes equations on \( \Omega_2 \) by (cf. [4]):

\[
(3.2) \quad \sigma^0 = \sigma_0 = \ln \rho_0, \quad u^0 = u_0, \quad T^0 = T_0;
\]

then for \( n \geq 0 \), starting from \( \{\sigma^n, u^n, T^n\} \), we solve

\[
(3.3)_1 \quad \frac{\sigma^{n+\theta} - \sigma^n + \theta}{\theta \Delta t} + \nabla \cdot u^{n+\theta} = -u^n \cdot \nabla \sigma^n \quad \text{in} \quad \Omega_2,
\]

\[
(3.3)_2 \quad \frac{u^{n+\theta} - u^n}{\theta \Delta t} = -a\mu \Delta u^{n+\theta} + \beta \nabla \sigma^n + \theta = \Psi(\sigma^n, u^n, T^n) + b \mu \Delta u^n \quad \text{in} \quad \Omega_2,
\]

\[
(3.3)_3 \quad \frac{T^{n+\theta} - T^n}{\theta \Delta t} = \chi(\sigma^n, u^n, T^n) + b \nabla T^n \quad \text{in} \quad \Omega_2,
\]

with \( 0 < a, b < 1 \).

3.2. Time discretization of the matching problem via operator splitting.

We follow scheme of the follows:

\[
(3.6) \quad \varphi^0
\]

then for \( n \geq 0 \),
which the above

Stokes equations

equations on $\Omega_2$

with $0 < a, b < 1, a + b = 1$, satisfying (3.1). The boundary conditions will be specified later on.

3.2. Time discretization of the full potential equation.

We follow here the presentation in [5]. Let’s consider first a fully implicit time discretization scheme of the equations (2.16)-(2.19). This scheme is of the backward Euler type and is defined as follows:

(3.6) $\varphi^0$ and $\rho^0$ are given in $\Omega_1$.

then for $n \geq 0$, assuming that $\varphi^n$ and $\rho^n$ are known, we obtain $\varphi^{n+1}$ and $\rho^{n+1}$ from the solution of
\[
\rho^{n+1} - \rho^n + \nabla \cdot (\rho^{n+1} \nabla \phi^{n+1}) = 0 \quad \text{in} \quad \Omega_1,
\]
with \( \rho^{n+1} \) given by
\[
\rho^{n+1} = \rho_0 (1 - k (|\nabla \phi^{n+1}|^2 + 2 \phi^{n+1} - \phi^n))^{\alpha}.
\]

It follows from [6] that the above discretization is well suited to the numerical simulation of lifting transonic flow, subsonic at infinity. Indeed operator splitting ideas can also be applied here; our starting point is the fact that from (2.17) we have
\[
\frac{\partial \rho}{\partial t} = (-2k \alpha) \rho \rho_0 \left( \frac{\phi}{\rho_0} \right)^2 - \gamma \left( \nabla \phi \cdot \nabla \frac{\partial \phi}{\partial t} + \frac{\partial \phi}{\partial t} \right).
\]

Using (3.9), we can approximate (2.16)-(2.19) by the following \( \theta \)-scheme, variant of (3.6)-(3.8):

Initialization:
\[
\phi^0 \quad \text{and} \quad \rho^0 \quad \text{are given in} \quad \Omega_1.
\]

Then for \( n \geq 0 \), assuming that \( \phi^n \) and \( \rho^n \) are known, we obtain \( \{ \phi^{n+\theta}, \rho^{n+\theta} \}, \{ \phi^{n+1-\theta}, \rho^{n+1-\theta} \}, \{ \phi^{n+1}, \rho^{n+1} \} \) as follows:

Step 1: Solve, with respect to \( \phi^{n+\theta} \), the elliptic linear problem
\[
2k \alpha \rho_0 \left( \frac{\phi^n}{\rho_0} \right)^2 - \gamma \left( \nabla \phi^n \cdot \nabla \left( \frac{\phi^{n+\theta} - \phi^n}{\theta \Delta t} + \frac{\phi^n - \phi^{n-\theta} - 2 \phi^n}{\theta^2 |\Delta t|^2} \right) - \nabla \cdot \left( \rho^n \nabla \phi^{n+\theta} \right) = 0 \quad \text{in} \quad \Omega_1,
\]
then compute
\[
\rho^{n+\theta} = \rho_0 \left( 1 - k \left( |\nabla \phi^{n+\theta}|^2 + 2 \phi^{n+\theta} - \phi^n \right) \right)^{\alpha}.
\]

Step 2: Solve, with respect to \( \phi^{n+1-\theta} \), the (nonlinear) problem
\[
\rho^{n+1} = \rho_0 \left( 1 - k \left( |\nabla \phi^{n+1-\theta}|^2 + 2 \phi^{n+1-\theta} - \phi^n \right) \right)^{\alpha}.
\]
\[ (3.13) \quad \frac{\rho^{n+1} - \rho^n}{\Delta t} + \nabla \cdot \left( \rho^{n+1} - \nabla \varphi^{n+1} \right) = 0 \quad \text{in } \Omega_1. \]

where

\[ (3.14) \quad \rho^{n+1} - \rho^n = \rho_0 \left( 1 - k \left( \frac{|\nabla \varphi^{n+1}|^2 + 2 \frac{\varphi^{n+1} - \rho^{n+1} - \theta}{\theta \Delta t}}{(1 - \theta)(1 - 2\theta)|\Delta t|^2} \right) \right). \]

Step 3: Solve, with respect to \( \varphi^{n+1} \), the elliptic linear problem.

\[ (3.15) \quad \begin{cases} 
2k\alpha \rho_0 \left( \frac{\rho^{n+1}}{\rho_0} \right)^2 - \gamma \left( \nabla \varphi^{n+1} \cdot \nabla \left( \frac{\varphi^{n+1} - \rho^{n+1} - \theta}{\theta \Delta t} \right) \right) + \\
2(1 - 2\theta)\rho^{n+1} - (1 - \theta)\varphi^{n+1} + \theta \varphi^{n+1} \theta \Delta t \end{cases} \]

\[ \cdot \nabla \cdot \left( \rho^{n+1} - \nabla \varphi^{n+1} \right) = 0 \quad \text{in } \Omega_1; \]

then compute

\[ (3.16) \quad \rho^{n+1} = \rho_0 \left( 1 - k \left( \frac{|\nabla \varphi^{n+1}|^2 + 2 \frac{\varphi^{n+1} - \rho^{n+1} - \theta}{\theta \Delta t}}{(1 - \theta)(1 - 2\theta)|\Delta t|^2} \right) \right). \]

3.3. Time discretization for the coupling of the Compressible Navier-Stokes and Full Potential Equations.

3.3.1 Generalities.

The fundamental idea behind the coupling strategy to be described below is to require the matching of the subdomain solutions (as defined in Section 2) only for the solutions of the linear subproblems encountered at the various steps of the operator splitting methods discussed in the above sections. Consequently, we shall "freeze" the interface conditions for the nonlinear subproblems, using at the interface boundary values predicted from the previous linear step. The implementation of these principles is described in the following sections.
3.3.2 Description of the matching method.

With $\Delta t$ as above, we couple the $\theta$-schemes (3.2)-(3.5) and (3.10)-(3.16), according to the matching criteria of Section 2.

**Description of the algorithm:** Using previous notation, we obtain

**Step 0:** Initialization.

\[
\begin{align*}
\varphi^0 & \quad \text{and} \quad \rho^0 \text{ are given in } \Omega_1, \\
\sigma^0, u^0 & \quad \text{and} \quad \tau^0 \text{ are given in } \Omega_2.
\end{align*}
\]

Then for $n \geq 0$, \(\{\varphi^n, \rho^n\}\) and \(\{\sigma^n, u^n, \tau^n\}\) being known, we compute \(\{\varphi^{n+\theta}, \rho^{n+\theta}\}\), \(\{\sigma^{n+\theta}, u^{n+\theta}, \tau^{n+\theta}\}\), then \(\{\varphi^{n+1-\theta}, \rho^{n+1-\theta}\}, \{\sigma^{n+1-\theta}, u^{n+1-\theta}, \tau^{n+1-\theta}\}\), and finally \(\{\varphi^{n+1}, \rho^{n+1}\}, \{\sigma^{n+1}, u^{n+1}, \tau^{n+1}\}\) as follows:

**Step 1:** Solve the linear elliptic problem (3.11) with the boundary conditions

\[
\rho^{n+\theta} \frac{\partial \varphi^{n+\theta}}{\partial n} = -\rho_\infty \Phi^{n+\theta} \cdot n \quad \text{on } \Gamma_1, \quad \varphi^{n+\theta} = \psi^{n+\theta} \quad \text{on } \Gamma_1, \quad \text{to obtain } \varphi^{n+\theta}, \quad \text{and use (3.12)}
\]

to compute \(\rho^{n+\theta}\).

**Solve now system (3.3) with the boundary conditions**

\[
\begin{align*}
u^{n+\theta} &= 0 \quad \text{on } \Gamma_B, \quad n \cdot \frac{\partial \varphi^{n+\theta}}{\partial n} \quad \beta \sigma^{n+\theta} \quad n = -b \mu \frac{\partial \varphi^{n+\theta}}{\partial n} \quad \text{on } \Gamma_2, \quad \varphi^{n+\theta} = \psi^{n+\theta} \quad \text{on } \gamma_2, \\
\tau^{n+\theta} &= T_B \quad \text{on } \Gamma_B, \quad \frac{\partial \tau^{n+\theta}}{\partial n} \quad = 0 \quad \text{on } \Gamma_2, \quad \tau^{n+\theta} = \tau^{n+\theta} \quad \text{on } \gamma_2.
\end{align*}
\]

In (3.18)-(3.20) the traces $\psi^{r+\theta}, \varphi^{n+\theta}, \tau^{n+\theta}$ are chosen such that
(3.21) \[ \tau_{1}^{n+\theta} = 0, \tau_{2}^{n+\theta} = 0, \tau_{3}^{n+\theta} = 0 \]

(in a least squares sense at least).

Step 2: Next, we look for \( \varphi^{n+1-\theta} \) and \( \sigma^{n+1-\theta} \), \( u^{n+1-\theta} \), \( T^{n+1-\theta} \) solutions of the nonlinear problems (3.13) and (3.4), for the following boundary conditions:

\[ \rho^{n+1-\theta} \frac{\partial \varphi^{n+1-\theta}}{\partial n} = \rho_{\infty} u_{\infty} n \text{ on } \Gamma_{1}, \varphi^{n+1-\theta} = \psi^{n+\theta} \text{ on } \gamma_{1}, \]

\[ \sigma^{n+1-\theta} = \sigma^{n+\theta} \text{ on } \gamma_{2} \cup \Gamma_{B}, \]

\[ u^{n+1-\theta} = v^{n+\theta} \text{ on } \gamma_{2}, u^{n+1-\theta} = 0 \text{ on } \Gamma_{B}, \]

\[ b_{u} \frac{\partial u^{n+1-\theta}}{\partial n} = \beta \sigma^{n+\theta} - a_{u} \frac{\partial \varphi^{n+\theta}}{\partial n} \text{ on } \Gamma_{2}, \]

\[ T^{n+1-\theta} = r^{n+\theta} \text{ on } \gamma_{2}, T = T_{B} \text{ on } \Gamma_{B}, \frac{\partial T^{n+1-\theta}}{\partial n} = 0 \text{ on } \Gamma_{2}. \]

Step 3: Finally we compute \( \varphi^{n+1} \) and \( \sigma^{n+1} \), \( u^{n+1} \), \( T^{n+1} \) as the solutions of the linear systems (3.15) and (3.5), respectively, with \( n \) and \( n+\theta \) replaced by \( n+1-\theta \) and \( n+1 \) in the boundary conditions (3.18) and (3.19), (3.20).

\[ \square \]

Solution methods for solving the nonlinear problems in Step 2 are discussed in [5] and [7] (see also [8], [9] for the solution of the nonlinear potential flow problem); these methods are based on either least squares/conjugate gradient algorithms, or on GMRES type iterative methods (see [3]). In the following Section 4, we shall concentrate on the solution of the matching problems of Steps 1 and 3.

4. Solution of the matching problems.

4.1 Generalities.

In view of solving the matching problems associated to steps 1 and 3 of the algorithm described in Section 3.3.2 it is quite convenient to see them as control problems (cf., e.g., [1]) and to take as control variables the respective traces of the variables \( \varphi \) and \( \{u, T\} \) on \( \gamma_{1}, \gamma_{2} \), respectively (we drop the superscripts \( n+\theta \) and \( n+1 \)); we shall denote these traces by \( \psi \) and \( \{v, r\} \). Once these traces
have been specified, then \( \varphi \) and \( \{u, T\} \) are uniquely defined as solutions of linear problems of the following type

\[
\begin{align*}
(4.1)_1 & \quad a_0 \nabla \cdot (a_1 \nabla \varphi) + A_2 \cdot \nabla \varphi = f_1 \text{ in } \Omega_1, \\
(4.1)_2 & \quad \varphi = \psi \text{ on } \Gamma_1, \\
(4.1)_3 & \quad a_1 \frac{\partial \varphi}{\partial n} = g_1 \text{ on } \Gamma_1
\end{align*}
\]

(4.2)_1 \quad \alpha \sigma + \nabla \cdot u = f_2 \text{ in } \Omega_2,
(4.2)_2 \quad a u - a \mu \Delta u + \beta \nabla \sigma = g_2 \text{ in } \Omega_2,
(4.2)_3 \quad \sigma = a \Pi \Delta T = h \text{ in } \Omega_2,
(4.2)_4 \quad \{u, T\} = \{v, \tau\} \text{ on } \Gamma_2,
(4.2)_5 \quad u = 0, T = T_B \text{ on } \partial B,
(4.2)_6 \quad a \mu \frac{\partial u}{\partial n} - \beta \sigma n = k, T = T_\infty \text{ on } \Gamma_2.

The above problems are discretized by the finite element methods discussed in [7], [5], [10], where a careful discussion of the compatibility between the spaces used for approximating \( \sigma \) and \( \sigma \) is given.

The matching conditions taking place on the overlapping region \( \Omega_{12} \) are achieved by

\[
(4.3) \quad \min \{\psi, v, \tau\} \quad J(\varphi, \sigma, u, T),
\]

with \( \varphi, \sigma, u, T \) obtained from \( \psi, v, \tau \) via the solution of the elliptic system (4.1), (4.2).

A possible candidate for \( J \) is given in Section 2 by (2.31); this minimization can be achieved by a conjugate gradient algorithm. Another alternative is based on the use of the GMRES algorithm and is defined as follows:

Considering the residuals associated to the matching problem we force them to zero, via a GMRES technique (described in Section 5). This GMRES algorithm is quite efficient in practice, but it has however some limitations that we would like to comment since they have practical implications. If the matching was perfect over \( \Omega_{12} \) we should have

\[
\int_{\Omega_{12}} (\nabla \cdot (a \nabla \varphi)) M \text{ d}x + \int_{\Omega_{12}} A_2 \cdot \nabla \varphi \cdot M \text{ d}x = \int_{\Omega_{12}} f_1 \cdot M \text{ d}x
\]
\begin{align}
(4.4) \quad & \int_{\Omega_{12}} (\nabla \varphi - u) \cdot \nabla w \, dx = 0, \forall w \in H^1(\Omega_{12}), \\
(4.5) \quad & \int_{\Omega_{12}} (\nabla \varphi - u) \cdot z \, dx = 0, \forall z \in \left( L^2(\Omega_{12}) \right)^N, \\
(4.6) \quad & \int_{\Omega_{12}} \left( T - T(\varphi) \right) \theta \, dx = 0, \forall \theta \in L^2(\Omega_{12}).
\end{align}

Satisfying (4.4) - (4.6) in a least squares sense by adjusting the "control" variables \( \psi, v \) and \( \tau \) (defined over the interface \( \gamma_1 \) and \( \gamma_2 \)) is always possible whatever \( \Omega_{12} \) is; on the other hand solving (4.4) - (4.6) via GMRES seems to require that after an appropriate discretization, the number of residual equations has to be equal to the dimension of the control space; the limitations resulting from that constraint will appear clearly once we shall have defined the finite element spaces used to approximate \( \varphi, u, \sigma, T \).

4.2 Finite Element Approximations

To approximate \( \varphi, u, \sigma, T \) we shall use the finite element spaces defined as follows:

1) Define a global triangulation \( \mathcal{T}_h \) of the computational domain \( \Omega_h = \Omega_{1h} \cup \Omega_{2h} \).
2) Define the triangulations \( \mathcal{T}_{1h} \) and \( \mathcal{T}_{2h} \) of \( \Omega_{1h} \) and \( \Omega_{2h} \), respectively, in such a way that \( \mathcal{T}_{1h} \) and \( \mathcal{T}_{2h} \) coincide on \( \Omega_{12h} = \Omega_{1h} \cap \Omega_{2h} \).
3) Starting from \( \mathcal{T}_h \), we define \( \mathcal{T}_{h/2} \) as the triangulation obtained from \( \mathcal{T}_h \) by subdividing each triangle \( K \in \mathcal{T}_h \) into 4 subtriangles, by joining the mid-points of each edge of \( K \). Similarly we define \( \mathcal{T}_{1h/2} \) and \( \mathcal{T}_{2h/2} \).
4) The potential \( \varphi \) will be approximated on \( \Omega_{1h} \), using the finite element space \( V_{1h} \) defined by

\begin{equation}
V_{1h} = \left\{ w_h \mid w_h \in C^0(\Omega_{1h}), w_h \mid K \in P_1, \forall K \in \mathcal{T}_{1h/2} \right\}.
\end{equation}

5) The temperature \( T \) and logarithmic density \( \sigma \) will be approximated on \( \Omega_{2h} \), using the space \( Q_{2h} \) defined by
\[ Q_{2h} = \{ q_h \mid q_h \in C^0(\Omega_{2h}), q_h \mid K \in P_1, \forall K \in \mathcal{T}_{2h} \}. \]

6) The velocity \( u \) will be approximated on \( \Omega_{2h} \), using the finite element space \( V_{2h} \) defined by
\[ V_{2h} = \{ s_h \mid s_h \in C^0(\Omega_{2h}), s_h \mid K \in P_1 \times P_1, \forall K \in \mathcal{T}_{2h/2} \}. \]

In (4.7)-(4.9), \( P_1 \) denotes the space of the two variable polynomials of degree \( \leq 1 \).

Using the above spaces, it is fairly easy to approximate the various boundary value problems providing \( \varphi_h, \sigma_h, u_h, T_h \), respective approximations of \( \varphi, \sigma, u, T \) (see [5] for the details; see also [7] for the finite element approximation of the compressible Navier-Stokes equations, using spaces similar to \( Q_{2h} \) and \( V_{2h} \)).

Next we approximate (4.4) - (4.6) as follows: We introduce first the following subspaces
\[ W_{1h}, R_{2h}, W_{2h} \] of \( V_{1h}, Q_{2h}, V_{2h} \), respectively (these spaces can be seen as the control spaces since they will contain the extensions over \( \Omega_{12h} \) of the unknown traces \( \psi_h, v_h \) and \( \tau_h \).)

Actually \( W_{1h} \) (resp. \( R_{2h}, W_{2h} \)) are by definition generated by those basis functions of \( V_{1h} \) (resp. \( Q_{2h}, V_{2h} \)) associated to the vertices of \( \mathcal{F}_{1h/2} \) (resp. \( \mathcal{F}_{2h}, \mathcal{F}_{2h/2} \)) belonging to \( \gamma_1 \) (resp. \( \gamma_2 \)); these various notions have been visualized on Figure 4.1.

![Figure 4.1: Detail of the overlapping region and of its triangulation.](image)

We have indicated in particular the support of the basis function of \( W_{1h} \) (resp. \( R_{2h}, W_{2h} \)) associated to \( M_i \in \Omega_{1h} \).

The discrete
\[ (4.10) \quad \int_{\Omega_{12}} \psi_h \]
\[ (4.11) \quad \int_{\Omega_{12}} \partial_{n_i} \]

We shall respectively and the unknown trc written as
\[ (4.13) \quad F_h (\psi) \]

where \( F_h \) is obta GMRES algorithm

5. On the GMRF 5.1 Generalities.

Instead of the following prob
\[ (5.1) \quad F(u) : \]

where \( F \) is a (po suppose that \( V \) is
associated to $M_1 \in \gamma_1$ (resp. $M_2$, $M_3 \in \gamma_2$).

The discrete form of (4.4) - (4.6) is given by (we dropped the $h$ in $\Omega_{12h}$):

\begin{align}
(4.10) \quad & \int_{\Omega_{12}} (\nabla \varphi_h - u_h) \cdot \nabla w_h \, dx = 0, \quad \forall w_h \in W_{1h}, \\
(4.11) \quad & \int_{\Omega_{12}} (\nabla \varphi_h - u_h) \cdot \tau_h \, dx = 0, \quad \forall \tau_h \in W_{2h}, \\
(4.11) \quad & \int_{\Omega_{12}} \left( T_h - T(\varphi_h) \right) \cdot \theta_h \, dx = 0, \forall \theta_h \in R_{2h}.
\end{align}

We shall restrict the relations (4.10) - (4.11) to the basis functions of $W_{1h}$, $W_{2h}$, $R_{2h}$, respectively and therefore obtain a number of (nonlinear) equations which is equal to the dimension of the unknown trace vector $\{ \psi_h, \nu_h, \tau_h \}$. In abstract form the matching problem can finally be written as

\begin{align}
(4.13) \quad & F_h (\psi_h, \nu_h, \tau_h) = 0.
\end{align}

where $F_h$ is obtained from the left hand sides of (4.10), (4.11), (4.12). The solution of (4.13) by a GMRES algorithm is addressed in the following Section 5.

5. On the GMRES solution of problem (4.13).

5.1. Generalities.

Instead of considering problem (4.13), directly, we shall consider first the GMRES solution of the following problem

\begin{align}
(5.1) \quad & F(u) = 0,
\end{align}

where $F$ is a (possibly nonlinear) operator from a *real Hilbert space* $V$ into its dual space $V^*$; we suppose that $V$ is equipped with the scalar product $\langle \cdot, \cdot \rangle$ and the corresponding norm $\| \cdot \|$. We denote
by $<\cdot, \cdot>$ the duality pairing between $V'$ and $V$, and by $S: V \to V'$ the associated duality isomorphism, i.e.

$$<Sv, w> = (v, w), \forall v, w \in V,$$
$$<Sv, w> = <S\bar{w}, v>, \forall v, w \in V,$$
$$<f, S^{-1} g> = (f, g), \forall f, g \in V'.$$

5.2. Description of the GMRES algorithm for solving (5.1):

(5.2) $u^0 \in V$ is given;

then for $n \geq 0$, $u^n$ being known we obtain $u^{n+1}$ as follows:

(5.3) $r^n_1 = S^{-1} F(u^n),$

(5.4) $w^n_1 = r^n_1 / \|r^n_1\|;$

Then for $j = 2, \ldots, k$, compute $r^n_j$ and $w^n_j$ by

(5.5) $r^n_j = S^{-1} DF(u^n; w^n_{j-1}) - \sum_{i=1}^{j-1} b_{i,j-1} w_i^n,$

(5.6) $w^n_j = r^n_j / \|r^n_j\|;$

in (5.5), $DF(u^n; w)$ is defined by either

(5.7) $DF(u^n; w) = F'(u^n) \cdot w$

(with $F'(u^n)$ the differential of $F$ at $u^n$) or if the exact calculation of $F'$ is too costly by

(5.8) $DF(u^n; w) = \frac{F(u^n + \varepsilon w) - F(u^n)}{\varepsilon },$

with $\varepsilon$ sufficiently small. We define then

Next, we solve

Next, we solve

and we define

Do $n = n + 1$

In alg

Remark 5.1:

Remark 5.2: derivative

Actually we differentiate

Remark 5.3:

indeed we have
(5.9) \[ \begin{align*}
\text{b}^n_i &= \langle \text{DF}(u^n; w^n) , w^n_i \rangle, \\
&= \langle S^{-1} \text{DF}(u^n; w^n) , w^n_i \rangle.
\end{align*} \]

Next, we solve the \( k \)-dimensional problem:

\[
\begin{align*}
\text{Find } a^n = \{a^n_j\}_{j=1}^k \in \mathbb{R}^k, \text{ such that, } \forall b = \{b_j\}_{j=1}^k \in \mathbb{R}^k \text{ we have }
\end{align*}
\]

\[
\begin{align*}
&||F(u^n + \sum_{j=1}^k a^n_j w^n_j)||_* \leq ||F(u^n + \sum_{j=1}^k b_j w^n_j)||_*, \\
\text{and we define } u^{n+1} \text{ by }
\end{align*}
\]

\[
\begin{align*}
u^{n+1} = u^n + \sum_{j=1}^k a^n_j w^n_j. \quad \Box
\end{align*}
\]

Do \( n = n+1 \) and go to (5.3). \( \Box \)

In algorithm (5.2)-(5.11), \( k \) is the dimension of the so-called Krylov space.

**Remark 5.1:** We should prove that

\[
\begin{align*}
(w^n_i , w^n_j) = 0, \quad \forall \; 1 \leq i, j \leq k, \; j \neq i.
\end{align*}
\]

**Remark 5.2:** To compute \( \text{DF}(u^n; w) \), we can use instead of (5.8), the second order accurate discrete derivative

\[
\begin{align*}
\text{DF}(u^n; w) = \frac{F(u^n + \varepsilon w) - F(u^n - \varepsilon w)}{2\varepsilon}.
\end{align*}
\]

Actually we are considering computing \( \text{DJ}(u^n; w) \) within machine precision using the alternative differentiation procedures discussed in, e.g., [11] (see also the references therein).

**Remark 5.3:** In (5.10), the norm \( || . ||_* \) satisfies the following relations

\[
\begin{align*}
||f||_* = ||S^{-1} f|| = \langle f, S^{-1} f \rangle^{1/2}, \quad \forall f \in V^d;
\end{align*}
\]

indeed we have used (5.14) to evaluate the various norms \( || . ||_* \) occurring in (5.10).
Remark 5.4: In order to evaluate \( a^B \) via the solution of (5.11), it is sufficient to approximate in the neighborhood of \( b=0 \), the functional

\[
b \rightarrow \| F(u^n + \sum_{j=1}^k b_j w_j^n) \|_\ast^2,
\]

by the quadratic one defined by

\[
b \rightarrow \| F(u^n) + \sum_{j=1}^k b_j DF(u^n; w_j^n) \|_\ast^2.
\]

Solving (5.16) is clearly equivalent to solving a linear system whose matrix \( k \times k \) is symmetric and positive definite (this approach is equivalent to taking for \( a^B \) the first iterate provided by Newton’s method applied to the solution of (5.15) and initialized with \( b=0 \)).

5.3. Application to the solution of problem (4.13).

In this paragraph, we shall identity - for convenience - the trace functions \( \varphi_h \), \( \gamma_h \), \( \tau_h \) with their, respective, (unique) extension over \( \Omega_{12} \) belonging to \( W_{1h}, W_{2h}, R_{2h} \). Therefore in the particular case of problem (4.13), the product space \( W_{1h} \times W_{2h} \times R_{2h} = \mathcal{V}_h \) plays the role of the space \( V \) of sections 5.1, 5.2. As scalar product over \( \mathcal{V}_h \) we have considered

\[
\left\langle \varphi_1, \varphi_2, \gamma_1, \gamma_2, \tau_1, \tau_2 \right\rangle = \int_{\Omega_{12}} \left( \nabla \varphi_1 \cdot \nabla \varphi_2 + \gamma_1 \varphi_1 \gamma_2 + \tau_1 \varphi_2 \tau_2 \right) dx,
\]

other choices are possible. Once (5.17) and the corresponding norm have been selected to provide \( \mathcal{V}_h \) with an Euclidean structure, applying the GMRES algorithm of Section 5.2 is fairly easy; we have to observe, however, that

\[
\begin{aligned}
&<F_h(\varphi_h, \psi_h, \gamma_h, \tau_h, w_h, s_h, \theta_h)>_h = \\
&\int_{\Omega_{12}} \left[ (\nabla \varphi_h - u_h) \cdot \nabla w_h + (\nabla \varphi_h - u_h) \cdot s_h + (T_h - T(\varphi_h)) \theta_h \right] dx,
\end{aligned}
\]

6. Numerical I

In this section, the details of the numerical experiments are discussed in the problems are nonlinear.

(i) A steady

(ii) An unsteady

6.1. Application

We consider the Reynolds number and triangulation error.

velocity grid is used to model the contours for the location between \( \Delta t = 0.1 \) for the \( t \) contours for the and Figure 6.6 have shown that and lower airfoil.

On Figure 6.6, the algorithm corresponds to …
and to specify the analogue of \( S \), i.e. the *preconditioning operator*. Concerning this last point we have experimented two operators \( S_h \), the first one, \( S_{1h} \), is associated to the scalar product (5.17), and in matrix form it will clearly have a block diagonal structure; the second operator, \( S_{2h} \), is obtained by simply taking the (scalar) diagonal of \( S_{1h} \), i.e.

\[
(5.19) \quad S_{2h} = \text{diag}(S_{1h}).
\]

In this section we shall present the results of numerical experiments in which the methodology discussed in the above sections has been applied to the solution of two test problems. These two problems are namely

(i) A steady viscous flow around and inside a bi-NACA 0012 twin airfoil.

(ii) An unsteady viscous flow at high incidence around and inside an idealized two dimensional air intake.

6.1. Application to the bi-NACA 0012 twin airfoil.

We consider here an internal/external flow associated to the bi-NACA 0012 twin airfoil shown in Figures 6.1, 6.2. The angle of attack is 6 degrees, the Mach number at infinity is .55 and the Reynolds number based on the distance between the two airfoils is 200. Figure 6.1 shows the density triangulation employed to compute a global Navier-Stokes solution to be used as a reference (the velocity grid is twice finer); Figure 6.2 shows the subregion \( \Omega_2 \) where the Navier-Stokes equations are used to model the flows together with the strip where the viscous and inviscid solutions are matched, located between \( \gamma_1 \) and \( \gamma_2 \). The steady solution has been obtained via a time dependent process using \( \Delta t = .1 \) for the \( \theta \)-scheme and running 100 time cycles \((t=10)\). Figures 6.3 and 6.4 show the Mach contours for the global Navier-Stokes solution and the matched one, respectively; the agreement between these two calculations is quite good. Similarly, one has shown on Figure 6.5 (global solution) and Figure 6.6 (matched solution) the density contours; they agree quite well. On Figures 6.7-6.10 we have shown the skin friction coefficients (cf) and then the heat transfer coefficients (ch) for the upper and lower airfoils. Again the agreement between global and matched solutions is quite satisfactory.

On Figure 6.11 we have compared the efficiency of the matching algorithm, using the GMRES algorithm combined with the various preconditioners discussed in Section 5. The slowest algorithm corresponds to \( S_h = \text{Identity} \), the intermediate to \( S_{1h} \) and the fastest to \( S_{2h} \) (block diagonal); using
S_{2h} leads to a speed up of two, measured in CPU, compared to the global solution calculation. Indeed further speed up can be obtained using parallel machines.

6.2. Application to an air intake.

For this test problem the geometry of the air intake is the one shown on Figures 6.12 and 6.13, where the corresponding density grids have also been visualized (for the global domain on Figure 6.12, for the Navier-Stokes domain \( \Omega_2 \) in Figure 6.13). The above grid has been used to accurately simulate an unsteady flow at \( Re=200, M_\infty=.6 \) for a 30 degrees angle of attack; for such data the flow is unsteady. We have used here \( \Delta t=.1 \), and Figures 6.14, 6.15 show the Mach contours of the reference global Navier-Stokes solution and of the matched one after 100 time cycles (\( t=10 \)). Finally we compare on Figures 6.16, 6.17 the vorticity contours produced by the Navier-Stokes reference calculation, and the viscous/inviscid one.

Again we observe a very good agreement between the results obtained from both methods. More details, test cases and performance analysis can be found in [5].

7. Conclusion.

In the case of incompressible fluids, it was shown in [2] that domain decomposition provide robust and accurate methods for the coupling of mathematical models of a given physical phenomenon. From the results presented in this paper a similar conclusion can be drawn for the more complicated case addressed in this paper where compressibility is taken into account.

Nevertheless, there is still room for many improvements such as efficient preconditioners, adaptive localization of the matching regions, efficient parallel implementations. It is our intention to extend these type of methods to the coupling of more complicated models, such as Euler and Navier Stokes equation or Boltzmann and Euler and/or Navier Stokes equations.
